Procedure A: The flask was charged with toluene (25 mL), then heated to 80 C under nitrogen. After 2 h the mixture was cooled and filtered through a pad of Celite, rinsing with toluene.
The filtrate was concentrated to give the crude product as a pale oil.
Purification by column chromatography afforded the title compound.

Procedure B: A vial was charged with acetonitrile (5 mL) and the substrate (0.50 mmol). The solution was stirred at room temperature for 16 h, then diluted with water (10 mL) and extracted with ethyl acetate. The organic layer was dried and concentrated to dryness to yield the product as a white solid (92%).
